

# The Form of The Friendly Number of 10

Sourav Mandal

souravmandal1729@gmail.com

## Abstract

Any positive integer  $n$  other than 10 with abundancy index  $\frac{\sigma(n)}{n}$  must be a square with at least 6 distinct prime factors, the smallest being 5, and my new argument about the form of the friendly number of 10 is  $\frac{25(5^{2c+1}-1)(8n+1-2c)}{4}$ , if exist. Further at least one of the prime factors must be congruent to 1 modulo 3 and appear with an exponent congruent to 2 modulo 6 in the prime factorization of  $n$ .

## I. Introduction

For a positive integer  $n$ , the sum of the positive divisors of  $n$  is denoted by  $\sigma(n)$ ; the ratio  $\frac{\sigma(n)}{n}$  is known as the abundancy index of  $n$  or sometimes the ratio denoted as  $\hat{\sigma}(n)$  or  $I(n)$ . A pair  $(a, b)$  is called a friendly pair if  $\hat{\sigma}(a) = \hat{\sigma}(b)$  in this case, it is also common to say that  $b$  is a friend of  $a$  or simply that  $b$  and  $a$  are friend. Perfect numbers have abundancy index 2, and thus all friendly numbers with abundancy index less than 2 are often called deficient, while numbers whose abundancy index are greater than 2 are called abundant. The original problem was to show that the density of friendly integers  $\mathbb{N}$ , is unity and the density of solitary numbers (numbers with no friends) is zero.

We used two main approaches: one was an analysis of the  $\frac{\sigma(n)}{n}$  function. While the other used number theoretic arguments to find a representation for a friend of 10. In [1], it was shown that 10 is the smallest number where it is unknown whether there are any friends of it. We will assume a basic understanding of the function  $\sigma(n)$ . This can be found in [2]. For more on number theoretic techniques, see [3]. And the question “Is 10 a solitary number” is still unanswered. If 10 does have a friend, the following may be of use in finding it.

### 1. Elementary Properties of Abundancy Index:

Let  $a$  and  $b$  be positive integers. In what follows, all primes are positive.

1.  $I(a) \geq 1$  with equality only if  $a=1$
2. If  $a$  divides  $b$  then  $I(a) \leq I(b)$  with equality only if  $a=b$
3. If  $p_1, p_2, \dots, p_k$  are distinct primes and  $e_1, e_2, \dots, e_k$  are positive integers then

$$I\left(\prod_{j=1}^k p_j^{e_j}\right) = \prod_{j=1}^k \left(\sum_{i=0}^{e_j} p_j^{-i}\right)$$

$$= \prod_{j=1}^k \frac{p_j^{e_j+1} - 1}{p_j^{e_j}(p_j - 1)}$$

These formulae follow from well-known analogues for  $\sigma$ :

$$\sigma\left(\prod_{j=1}^k p_j^{e_j}\right) = \prod_{j=1}^k \left(\sum_{i=0}^{e_j} p_j^i\right)$$

$$= \prod_{j=1}^k \frac{p_j^{e_j+1} - 1}{(p_j - 1)}$$

Property 3 directly implies a property of  $I$  shared by  $\sigma$ .

4.  $I$  is weakly multiplicative (meaning, if  $\gcd(a, b) = 1$ , then  $I(ab) = I(a)I(b)$ ).
5. Suppose that  $p_1, p_2, \dots, p_k$  are distinct primes,  $q_1, q_2, \dots, q_k$  are distinct primes  $e, e_2, \dots, e_k$  are positive integers and  $p_j \leq q_j, j = 1, 2, 3, \dots, k$  then

$$I\left(\prod_{j=1}^k p_j^{e_j}\right) \geq I\left(\prod_{j=1}^k q_j^{e_j}\right)$$

With equality only if  $p_j = q_j, j = 1, 2, \dots, k$ . This follows from 3 and the observation that if  $e \geq 1$ , then  $\frac{x^{e+1}-1}{x^e(x-1)}$  is a decreasing function of  $x$  on  $(1, \infty)$ .

6. If the distinct prime factors of  $a$  are  $p_1, p_2, \dots, p_k$ , then  $I(a) < \prod_{j=1}^k \frac{p_j}{p_j-1}$ . Although related to 5,7 is most easily seen by applying 3 and the observation that for  $p > 1$ ,

$$\frac{p^{e+1} - 1}{p^e(p - 1)} = \frac{p - \frac{1}{p^e}}{p - 1}$$

Increases to  $\frac{p}{p-1}$  as  $e \rightarrow \infty$ .

## II. Theorem 1:

If  $n$  is a friend of 10 then  $n$  is an odd square number with at least 6 distinct prime factors, the smallest being 5. Further, at least one of  $n$ 's prime factors must be congruent to 1 modulo 3, and appear in the prime power factorization of  $n$  to a power congruent to 2 modulo 6. If there is only one such prime dividing  $n$ , then it appears to a power congruent to 8 modulo 18 in the factorization of  $n$ .

**Proposition 1.**  $I(an) > I(n)$  for  $a > 1$

**Proof.** In general  $a$  can share prime factors with  $n$ . Let  $a = uv$  where  $\gcd(a, n) = u, \gcd(v, n) = 1$ . We thus have  $I(an) = I(un)I(v)$  by Elementary properties of Abundancy Index.

$$I(an) = I(un)I(v) > I(un)$$

$$I(un) > I(n)$$

Thus,

$$I(an) > I(n) \text{ for } a > 1$$

**Lemma 1.** A friend of  $n$  cannot be a multiple of  $n$ . That is  $\frac{\sigma(n)}{n} \neq \frac{\sigma(an)}{an}$  for  $a > 1$

**Proof.** This follows directly from proposition 1. Since  $an$  is a multiple of  $n$ .  $\frac{\sigma(an)}{an} > \frac{\sigma(n)}{n}$ ,

So  $\frac{\sigma(n)}{n} \neq \frac{\sigma(an)}{an}$  for  $a > 1$

**Corollary 1.** A friend of 10 cannot be the form  $n = 2^a 5^b m$ . Thus a friend of 10 cannot be an even integer.

**Proof.** For  $a, b > 1$ .  $2^a 5^b$  is a multiple of 10, and  $\frac{\sigma(n)}{n} > \frac{9}{5}$

Therefore  $n$  is not a friend of 10. A friend of 10 must be of the form  $5^b m$ , So a friend of 10 can't be an even integer.

**Corollary 2.** A friend of 10 must be square of some numbers:  $n = 5^{2b} \prod_{j=1}^k p_j^{2e_j}$

**Proof.** Suppose  $\frac{\sigma(n)}{n} = \frac{9}{5}$  and  $n = 5^b d$ , Where  $d = \prod_{j=1}^k p_j^{e_j}$  then

$$\frac{\sigma(n)}{n} = \frac{9}{5}$$

$$5 \cdot \sigma(5^b) \sigma\left(\prod_{j=1}^k p_j^{e_j}\right) = (9) \cdot 5^b \prod_{j=1}^k p_j^{e_j}$$

$$5 \cdot \sigma(5^b) \cdot \sigma(p_1^{e_1}) \cdot \sigma(p_2^{e_2}) \cdot \sigma(p_3^{e_3}) \dots \sigma(p_k^{e_k}) = (9) \cdot 5^b \cdot p_1^{e_1} \cdot p_2^{e_2} \cdot p_3^{e_3} \dots p_k^{e_k}$$

$$(1 + 5 + \dots + 5^b)(1 + p_1 + \dots + p_1^{e_1}) \dots (1 + p_k + \dots + p_k^{e_k}) = (9) \cdot 5^{b-1} \cdot p_1^{e_1} \cdot p_2^{e_2} \cdot p_3^{e_3} \cdot p_k^{e_k}$$

From the corollary 1, we have  $p_i > 2$  for any  $i \leq k$ . So the right side must be odd. To obtain this, we must have that every sum on the left side is also odd. Since each  $p_i^{e_i}$  is odd, We must have an odd number of terms in the sum for the whole sum to be odd. To obtain this, each  $e_i$  and  $b$  must be even. Thus  $n$  must be the square of some numbers.

**Proposition 2.** If  $I(N^2) = \frac{9}{5}$ , then  $3 \nmid N^2$

**Proof.** From the corollary 2, we have that if  $I(N^2) = \frac{9}{5}$  and  $3 \mid N^2$ . Then

$$N^2 = 3^{2a} 5^{2b} \prod_{j=1}^k p_j^{2e_j}$$

Where  $2, 3, 5 \nmid \prod_{j=1}^k p_j^{2e_j}$ . It is easy to verify that  $I(3^2 5^4)$  and  $I(3^4 5^2) > \frac{9}{5}$ . Combining this with Lemma 1, we have that  $I(3^2 5^4 \prod_{j=1}^k p_j^{2e_j})$  and  $I(3^4 5^2 \prod_{j=1}^k p_j^{2e_j}) > \frac{9}{5}$

Thus, the problem reduces to a single case:  $I(3^2 5^2 \prod_{j=1}^k p_j^{2e_j}) = \frac{9}{5}$

$$5 \cdot \sigma(3^2) \cdot \sigma(5^2) \sigma \left( \prod_{j=1}^k p_j^{2e_j} \right) = 9 \cdot 3^2 \cdot 5^2 \cdot \prod_{j=1}^k p_j^{2e_j}$$

$$(13) \cdot (31) \cdot \sigma \left( \prod_{j=1}^k p_j^{2e_j} \right) = (3^4) \cdot (5) \cdot \prod_{j=1}^k p_j^{2e_j}$$

We can see that  $13, 31 \mid \prod_{j=1}^k p_j^{2e_j}$ , Thus  $\prod_{j=1}^k p_j^{2e_j} = 13^{2c} 31^{2d} \prod_{i=1}^h p_i^{2e_i}$

Where  $2, 3, 5, 13, 31 \nmid \prod_{i=1}^h p_i^{2e_i}$ . We will divide by 13, 31 immediately.

$$\sigma(13^{2c}) \sigma(31^{2d}) \sigma \left( \prod_{i=1}^h p_i^{2e_i} \right) = 3^4 (5) (13^{2c-1}) (31^{2d-1}) \prod_{i=1}^h p_i^{2e_i}$$

$$I \left( \prod_{i=1}^h p_i^{2e_i} \right) = \frac{405}{\frac{\sigma(13^{2c})}{13^{2c-1}} \cdot \frac{\sigma(31^{2d})}{31^{2d-1}}} < \frac{405}{448} < 1$$

This is a contradiction with Elementary properties of Abundancy Index (property no.1).

Hence,  $3 \nmid N^2$  whenever  $N^2$  is a friend of 10.

**Proposition 3.** If  $I(n) = \frac{9}{5}$ , then  $n = 5^{2a} \prod_{j=1}^k p_j^{e_j}$  where  $k \geq 4$

**Proof.**

Using the previous proposition and elementary properties of Abundancy Index (property no.6), We will construct the largest value of  $I(n^e)$  with 4 distinct primes. Let  $n = (5)(7)(11)(13)$

Here is a largest value with 4 distinct primes because from proposition 2. We have that  $p_i \geq 7$ .

To maximize the value of  $I(n^e)$  we let  $e \rightarrow \infty$ . Hence,

$$\lim_{e \rightarrow \infty} I(n^e) = \frac{5 \cdot 7 \cdot 11 \cdot 13}{4 \cdot 6 \cdot 10 \cdot 12} = \frac{1001}{576} < \frac{9}{5}$$

So, there must be at least 5 distinct primes in the factorization of  $n$ .

**Proposition 4.** If  $I(n) = \frac{9}{5}$ , then  $n = 5^{2a} \prod_{j=1}^k p_j^{e_j}$  where  $k \geq 5$

**Proof.**

We can use the same technique as in the last proposition to show that only 3 cases could work if  $n$  were represented as 5 distinct primes. These are  $n = (5^a 7^b 11^c 13^d 17^f)^2$  but this does not work because

The smallest it could be is:  $I(5^2 7^2 11^2 13^2 17^2) > \frac{9}{5}$ . Case2 gives  $n = (5^a 7^b 11^c 13^d 19^f)^2$ , but this does

not work because the smallest it could be:  $I(5^2 7^2 11^2 13^2 19^2) > \frac{9}{5}$ . The final case takes

a little more work:  $n = (5^a 7^b 11^c 13^d 23^f)^2$  We can see that if  $a > 1$ , then  $I(n) > \frac{9}{5}$ ,

so  $a = 1$ . Let us examine when  $I(n) = \frac{9}{5}$ , then

$$5\sigma(5^2)\sigma(7^{2b})\sigma(11^{2c})\sigma(13^{2d})\sigma(23^{2f}) = 9(5^2)(7^b 11^c 13^e 23^f)^2$$

$$31\sigma(7^{2b})\sigma(11^{2c})\sigma(13^{2d})\sigma(23^{2f}) = 9(5)(7^b 11^c 13^e 23^f)^2 = l$$

Clearly,  $31 \nmid l$ . Since the left hand side is some integer, this results in a contradiction. Hence a friend of 10 must be composed of at least 6 distinct primes.

Finally, since

If  $I(N^2) = 5^{2a} \prod_{j=1}^k p_j^{2e_j}$ , then

$$5\sigma(N^2) = 5(1 + 5 + \dots + 5^{2a}) \prod_{j=1}^k \left( \sum_{i=0}^{2e_j} p_j^i \right) = 9N^2,$$

We have that  $9 \mid \sigma(N^2)$ . If  $p \equiv 2 \pmod{3}$ , then  $\sigma(p^{2e}) \equiv 1 \pmod{3}$  for any positive integer  $e$ .

Consequently, some  $p_j \equiv 1 \pmod{3}$ , and  $\sigma(p_j^{2e_j}) \equiv 0 \pmod{3}$  implies  $2e_j + 1 \equiv 0 \pmod{3}$ .

Thus  $e_j = 3t + 1$  for some integer  $t$ , so  $2e_j = 6t + 2$

If  $p_j$  is only such prime dividing  $N^2$ , then  $\sigma(p_j^{2e_j}) \equiv 0 \pmod{9}$ . Checking the possibilities

$p_j \equiv 1, 4 \text{ or } 7 \pmod{9}$ , one finds that  $2e_j \equiv 8 \pmod{18}$

### III. Theorem 2:

If  $N^2$  is a friend of 10 then  $N^2$  must be in the form of  $\frac{25(5^{2c+1}-1)(8n+1-2c)}{4}$ .

**Proof.**

Let, the friendly number of 10 is  $N^2$

$$N^2 = 5^{2c} \prod_{j=1}^k p_j^{2e_j}$$

$$\frac{\sigma(N^2)}{N^2} = \frac{9}{5}$$

As  $N^2$  is a square number from corollary 2., So it is in the form of  $(4a + 1)$

$$\therefore 5|(4a + 1)$$

$\therefore N^2$  is in the form of  $(20a - 15)$

$$\frac{\sigma(20a - 15)}{20a - 15} = \frac{9}{5}$$

$$\Rightarrow \sigma(20a - 15) = -27 + 36a$$

$$\sigma(20a - 15) \equiv -27 \pmod{36}$$

&

$$\sigma(20a - 15) \equiv -27 \pmod{a}$$

Again  $(20a - 15)$  is a square number so  $a = 5a_0(a_0 - 1) + 2$

After putting  $a = 5a_0(a_0 - 1) + 2$ , we get  $(20a - 15) = (10a_0 - 5)^2$

Last digit of  $5a_0(a_0 - 1) + 2$  is always 2 so

$$\frac{\sigma(20a-15)+27}{36} = \frac{\sigma[(10a_0-5)^2]+27}{36} = a_1 \text{ here the last digit of } a_1 \text{ is must be 2}$$

$$\sigma[(10a_0 - 5)^2] \equiv -27 \pmod{36}$$

$$\sigma\left(5^{2c} \prod_{j=1}^k p_j^{2e_j}\right) \equiv -27 \pmod{36}$$

Here the last digit of the quotient is 2

Hence,

$$\sigma\left(\prod_{j=1}^k p_j^{2e_j}\right) \equiv 45 - 90c \pmod{360}$$

$$\Rightarrow \sigma\left(\prod_{j=1}^k p_j^{2e_j}\right) = 360n + 45 - 90c$$

$$\Rightarrow \sigma(5^{2c})\sigma\left(\prod_{j=1}^k p_j^{2e_j}\right) = \frac{(5^{2c+1} - 1)(360n + 45 - 90c)}{4}$$

$$\Rightarrow \sigma\left(5^{2c} \prod_{j=1}^k p_j^{2e_j}\right) = \frac{(5^{2c+1} - 1)(360n + 45 - 90c)}{4}$$

$$\begin{aligned} \therefore \frac{\sigma(N^2)}{N^2} &= \frac{9}{5} \\ \Rightarrow \frac{\sigma(5^{2c} \prod_{j=1}^k p_j^{2e_j})}{5^{2c} \prod_{j=1}^k p_j^{2e_j}} &= \frac{9}{5} \\ \Rightarrow \frac{(5^{2c+1} - 1)(360n + 45 - 90c)}{4(5^{2c} \prod_{j=1}^k p_j^{2e_j})} &= \frac{9}{5} \\ \Rightarrow 5^{2c} \prod_{j=1}^k p_j^{2e_j} &= \frac{25(5^{2c+1} - 1)(8n + 1 - 2c)}{4} \\ \Rightarrow N^2 &= \frac{25(5^{2c+1} - 1)(8n + 1 - 2c)}{4} \end{aligned}$$

So, we have come to the conclusion that the friendly number of 10 is must be in the form of

$$\begin{aligned} &\frac{25(5^{2c+1}-1)(8n+1-2c)}{4} \text{ if exists.} \\ N^2 &= \frac{25(5^{2c+1} - 1)(8n + 1 - 2c)}{4} \end{aligned}$$

From proposition 2.3  $3 \nmid N^2$

$$\begin{aligned} 3 \nmid (8n + 1 - 2c) \\ \therefore n \neq 3n_0 + (c - 2) \end{aligned}$$

Just for fun, we introduce a new definition.

**Definition 1:**(Theoretical Friend). A sequence  $n_e$  is a theoretical Friend of m if:

$$\lim_{e \rightarrow \infty} I(n_e) = I(m)$$

**Proposition 5.10** has at least one theoretical Friend, namely  $n_e = 3^e \cdot 5$

**Proof.**

$$\lim_{e \rightarrow \infty} I(n_e) = \lim_{e \rightarrow \infty} \frac{\sigma(3^e) \cdot \sigma(5)}{3^e \cdot 5}$$

$$= \left(\frac{3}{2}\right) \cdot \left(\frac{6}{5}\right) = I(10)$$

For further reading on the topic of  $I(n)$  and  $\sigma(n)$ , see [5] and [4]. See [5] for information concerning when  $\sigma(n) = k$  has exactly  $m$  solutions (Sierpiński conjecture). See [4] for a more in-depth study of  $\sigma(n)$  and on the distribution and density of numbers of this form.
